Lecture 8: Robot Perception

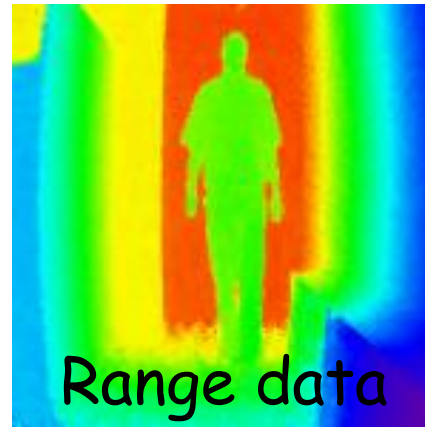

<http://pascallin.ecs.soton.ac.uk/challenges/VOC/databases.html#Caltech>

Given visual input, understand the information the input contains

- Object location: **object detection**
- Type of object: **object classification**
- Exact object name: **object recognition**
- Overall scene: **scene understanding**

Type of data

Structured light

$$x = \frac{b \cdot u}{f \cot(\alpha) + u} \quad z = \frac{b \cdot f}{f \cot(\alpha) + u}$$

$$\frac{\partial u}{\partial z} = G_p = \frac{b \cdot f}{z^2}$$

$$\frac{\partial \alpha}{\partial z} = G_a = \frac{b \sin(\alpha)^2}{z^2}$$

Near IR light source

Carmine 1.09

- Operating range: 0.35 m - 1.4 m
- Spatial resolution: 0.9 mm at 0.5m
- Depth resolution: 0.1 cm at 0.5m

Structured light

Segmentation: decomposition of an image into consistent regions

- Data that belong to the same region have similar properties
 - Similar color, texture, surface normal, etc.
- Data that belong to different regions have different properties
 - Different color, texture, surface normal, etc.
- Segmentation as clustering
 - Partitioning: divide an image into coherent regions
 - Grouping: group together elements of similar properties

- Divide an image into sensible regions using pixel intensity, color, texture, etc.
- Background subtraction
- Clustering
- Graph-based

Background subtraction

http://vip.bu.edu/files/2010/02/FDR_FPR_control_comparison1-594x636.jpg

- Subtract an estimate of the appearance of the background from the image
- Consider areas of large absolute difference to be foreground

Issues

- Obtaining a good estimate of the background is non-trivial
 - Changes in environment, lighting, weather, etc.
 - Use a moving average
- Threshold

Agglomerative clustering

- Consider each data point as a cluster
- Recursively merge the clusters with the smallest inter-cluster distance until the result is satisfactory

Agglomerative clustering

Issues

- Inter-cluster distance
 - Distance between closest elements
 - Distance between farthest elements
 - Average distance between elements
- Number of clusters

- Choose k data points as seed points
- Recursively assign each data point to the cluster whose center is the closest and recalculate the cluster mean until the center does not change
- Minimize the within cluster sum of squares
 - Tries to produce k clusters of equal size

K-means clustering

[http://en.wikipedia.org/wiki/Segmentation_\(image_processing\)](http://en.wikipedia.org/wiki/Segmentation_(image_processing))

Issues

- Segments are not connected in image
 - Using pixel coordinates would break up large regions
- Determining k is non-trivial

- Represent image as a graph, each pixel being a node of a graph
- Edges are formed between neighboring pixels
- Merge the nodes such that nodes belonging to the same segment more similar to one another than nodes at the boundary of two segments

- Internal difference of a cluster c :

- $Int(C) = \max_{e \in MST(C, E)} w(e)$

- Difference between clusters c_1, c_2 :

- $Dif(C_1, C_2) = \min_{v_i \in C_1, v_j \in C_2, (v_i, v_j) \in E} w((v_i, v_j))$

- Minimum internal difference:

- $MInt(C_1, C_2) = \min(Int(C_1) + \tau(C_1), Int(C_2) + \tau(C_2))$

- $\tau(C) = \frac{k}{|C|}$

- A boundary exists between c_1 and c_2 if $Dif(C_1, C_2) > MInt(C_1, C_2)$

Efficient graph-based image segmentation

Felzenszwalb, P. and Huttenlocher, D. 2004. "Efficient Graph-Based Image Segmentation"
International Journal of Computer Vision, Volume 59, Number 2.

- Regions of consistent properties are grouped together

Issues

- Number and quality of segments depend on the parameter k , smoothing factor, and minimum number of nodes

- Generally, we can use image segmentation algorithms by replacing intensity, color, or texture by depth, surface normal, etc.

Surface normal computation

$$\mathbf{x}_u \equiv \partial \mathbf{x} / \partial u$$

$$\mathbf{x}_v \equiv \partial \mathbf{x} / \partial v$$

$$N = \frac{1}{|\mathbf{x}_u \times \mathbf{x}_v|} (\mathbf{x}_u \times \mathbf{x}_v)$$

Ground segmentation

http://www-personal.acfr.usyd.edu.au/p.morton/media/img/data_ground.png

- Extract all points below a certain height

Issues

- Data are noisy
 - Objects will also lose information
- Wall cannot be segmented out
- Ground is not always planar

Plane segmentation

- Find a plane that minimize the average distance between a set of points and the surface
- Recursively merge the surface patches

Issues

- Not every object is planar
 - Curved objects will be segmented into several segments

Feature: a piece of information relevant for solving a computational task, e.g., locating an object in an image

- Raw data
- Histogram
- Pyramid of histograms
- Shape

- Compute a histogram of intensity or color
- Compute the correlation between example and test

Issues

- Loss of the structural information
- Dimensionality

Scale Invariant Feature Transform

Scale Invariant Feature Transform (SIFT)

- Identify locations and scales that are identifiable from different views of the same object
 - $L(x, y, \sigma) = G(x, y, \sigma) * I(x, y)$
 - $D(x, y, \sigma) = L(x, y, k\sigma) - L(x, y, \sigma)$
- Detect extrema (local minimum or maximum)

- Remove points of low contrast or poorly localized on an edge
- Orientation assignment

$$m(x, y) = \sqrt{(L(x + 1, y) - L(x - 1, y))^2 + (L(x, y + 1) - L(x, y - 1))^2}$$

$$\theta(x, y) = \tan^{-1} \frac{L(x, y + 1) - L(x, y - 1)}{L(x + 1, y) - L(x - 1, y)}$$

- Create a keypoint descriptor: 16 histograms (4x4 grid), each with 8 orientation bins, containing a total of 128 elements.

Histogram of Oriented Gradient

- Divide the image into small rectangular or radial cells
- Each cell accumulates a weighted local 1-D histogram of gradient directions over the pixels of the cell
- Normalize each cell by the energy over larger regions

- Compute eigenvectors: $\lambda_1, \lambda_2, \lambda_3$
 - Point/Spherical: $\lambda_1 \approx \lambda_2 \approx \lambda_3$
 - Planar: $\lambda_1 \approx \lambda_2 \gg \lambda_3$
 - Elongated: $\lambda_1 \gg \lambda_2 \approx \lambda_3$

Issues

- Many different objects have similar shape factor
- Shape factor of an object can depend on the point of view

- 2x2 or 3x3 matrix that captures both the orientation information and its confidence/saliency
 - Shape defines the type of information (point, surface, etc.)
 - Size represents the saliency
- Each token is first decomposed into the basis tensors, and then broadcasts its information to its neighbors.

- The magnitude of the vote decays with distance and curvature:

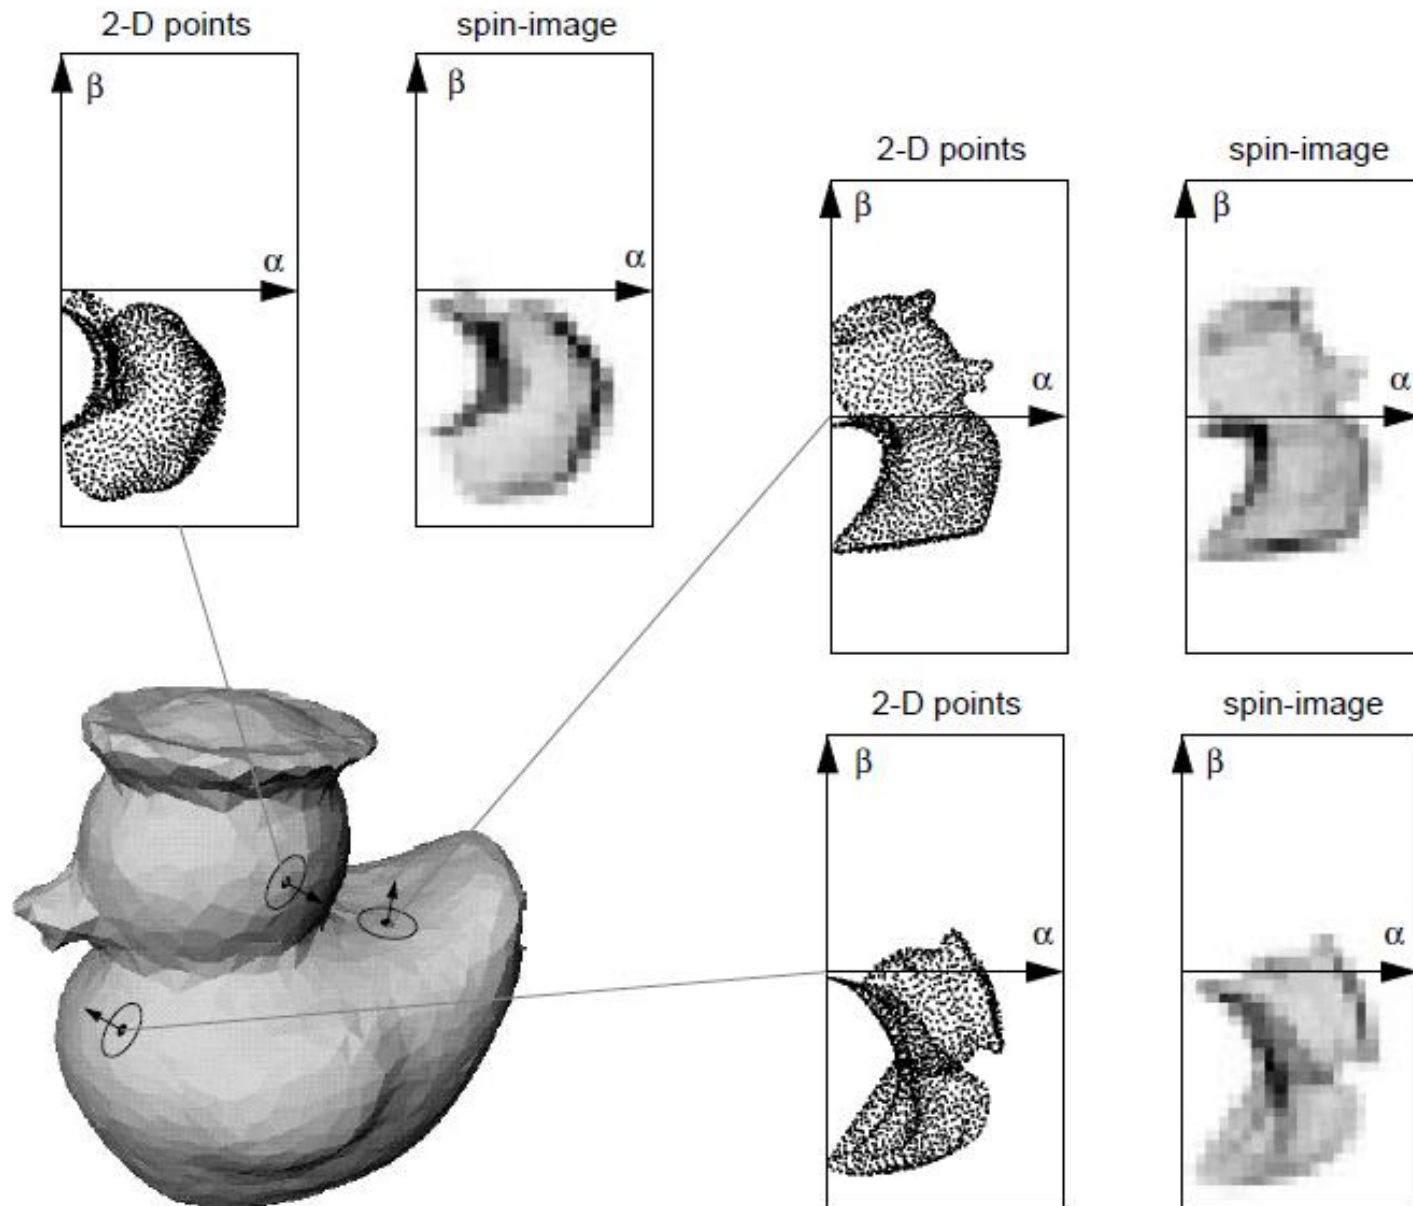

$$V(d, \rho) = e^{-\frac{d^2 + c\rho^2}{\sigma^2}}$$

- d is the distance along the smooth path
- ρ is the curvature of the path
- c controls the degree of decay
- σ controls the size of the voting neighborhood
- Accumulate the votes by adding the matrices
- Analyze the tensor by eigen decomposition

Johnson, A., Herbert, M., 1999. "Using Spin Images for Efficient Object Recognition in Cluttered 3D Scenes" IEEE Transactions on Pattern Analysis and Machine Intelligence, 21, (5).

Spin image

- Collect a histogram of points
 - The resolution of the histogram
 - The size of the histogram
- To compare two spin images P and Q
 - Compute the correlation between two images

$$R(P, Q) = \frac{N \sum p_i q_i - \sum p_i \sum q_i}{\sqrt{(N \sum p_i^2 - (\sum p_i)^2)(N \sum q_i^2 - (\sum q_i)^2)}}$$

- Can also apply PCA, remove the mean spin image and compute the Euclidean norm

- Take a set of labeled examples
- Determine a rule that assign a label to any new example using the labeled examples
- Training dataset (\mathbf{x}_i, y_i)
 - \mathbf{x}_i : measurements of the properties of objects
 - y_i : label
- Goal: given a new, plausible \mathbf{x} , assign it a label y .

$$p(k | \mathbf{x}) = \frac{p(\mathbf{x} | k) p(k)}{p(\mathbf{x})} \propto p(\mathbf{x} | k) p(k)$$

Given \mathbf{x}

➤ Assign label k to \mathbf{x} if

➤ $p(k | \mathbf{x}) > p(i | \mathbf{x})$ for all $i \neq k$ and $p(k | \mathbf{x}) > \text{threshold}$

➤ Assign a random k label between k_1, \dots, k_j if

➤ $p(k_1 | \mathbf{x}) = \dots = p(k_j | \mathbf{x}) > p(i | \mathbf{x})$ for all $i \neq k$

➤ Do not assign a label if

➤ $p(k | \mathbf{x}) > p(i | \mathbf{x})$ for all $i \neq k$ and $p(k | \mathbf{x}) \leq \text{threshold}$

Class conditional densities – $p(\mathbf{x} | k)$

- Modeling probability explicitly

- Determining decision boundaries directly

Nearest neighbor classifier

Given \mathbf{x}

- Determine M training example that are nearest: $\mathbf{x}_1, \dots, \mathbf{x}_M$
- Determine class k that has the largest representation n in the set
- Assign label k to \mathbf{x} if $n > \text{threshold}$
- Assign no label otherwise

Support Vector Machine

- Find a hyperplane that maximizes the margin between the positive and negative examples

- $w \cdot x_i + b \geq 1$: positive x_i
- $w \cdot x_i + b \leq -1$: negative x_i
- $w \cdot x_i + b = 1$: support vectors

- Classify a point: $f(x) = \text{sign}(w \cdot x + b)$

- For multiclass classification, one against all, one against one, etc.

Bag of Words

- Appearance
 - How much does a patch of image resemble a known part?
- Spatial relation
 - How well do the parts match the expected shape?

- Open Source Computer Vision Library for image and video processing
- The library has more than 2500 optimized algorithms, including both classic and state-of-the-art computer vision and machine learning algorithms

- Library for 2D/3D image and point cloud processing
- Contains numerous state-of-the-art algorithms including filtering, feature estimation, surface reconstruction, registration, model fitting and segmentation
